

## Ring network switches typically have multiple optical and electrical components

### Overview

Multiple rings share two or more common switches, forming a mesh-like structure. This topology supports large-scale, high-availability networks where different operational areas need local redundancy but also interconnection. A fiber optic ring network is a physical or logical network topology where devices (usually switches) are connected in a closed-loop using fiber optic cables. Data travels from node to node, with each node along the way handling every packet. Rings can be unidirectional, with all traffic. Industrial switches, as the core components of this infrastructure, play a pivotal role in establishing and maintaining the integrity of industrial ring networks. This article aims to provide a concise yet comprehensive overview of how industrial switches contribute to the formation of industrial. Ring topology is a network layout where each device connects to exactly two others, forming a closed loop for data to travel. When you're laying out a network, the topology you choose can significantly impact performance, reliability, and scalability.
