

Telecom optical splitter operation

Overview

At its core, a fiber optic splitter relies on the principles of light reflection, refraction, and waveguiding to divide signals. These unassuming devices enable a single optical signal to be divided into multiple paths, making them indispensable for sharing network resources efficiently—from residential FTTH (Fiber-to-the-Home) connections to large-scale telecom backbones. Understanding these components is essential for comprehending the inner workings of optical splitters. One important note is that splitting architectures should be seen as tools that can be mixed and matched to. An Optical Splitter, also known as a beam splitter, is a passive optical device that divides a single input optical signal into two or more output signals.
